D. King, Andrew .R. MacLeod, Hans Schimmer; publisher: Birkhauser Verlag [ISBN: 978-3-7643-1262-4]{} ; The use of the name 'biological cell' for the first time was incorrect. See Laubenbacher & Stadler (2000)[@Laubenbacher2000a] for a historical review of the rise and fall of the term biological cell. ]{} Abstract {#abstract.unnumbered} ----- [ A direct confrontation of the multitude of information accessible in the form of databases and the overwhelming amount of data is often a daunting task. Having ever clearer \*concepts\* of what we are talking about, however, could help to focus our efforts on \*what is really important\*, provided we are aware of how the concepts are defined. This is a very important issue if we want to stay on target. In order to find out what is important, we need to have a clear idea of what \*should be\* important, and what \*should not\*. It is clear that important information is present in all kinds of ways in the form of data. Such data are either available or simply in the process of being collected. The question is: How should one decide \*which\* aspects of information are important? This is, in fact, a really hard question, as no general answer to this question is possible. Nevertheless, we can obtain, from the collected data, some quantitative \*thoughts\* about this, which can still be regarded as an answer to the question. The interesting question, however, remains open: Which kind of qualitative answers, derived from the quantitative considerations, actually \*do\* provide insight into the biological world? ]{} Introduction ===== Recent years have been characterized by the tremendous progress of high-throughput technologies. These technologies offer the possibility of studying different aspects of the universe with unprecedented detail. One of the most important aspects is the study of complex biological systems, such as human genomes and proteomes. This is possible only with the development of computational tools and systems, which can help us to analyze and interpret the complexity of information in a given system. The data that are generated by high-throughput technologies are stored in databases, which are mainly relational. The enormous number of entries stored in databases makes it impossible to analyze such data immediately in a meaningful way, as the huge amount of information is not accessible by humans on a single occasion. 82157476af
